# Group Report Lab 8-Group 4

Maxime Bonneau, Martina Sandberg, Thomas Zhang 2015-12-14

### Assignment 1

We want to classify the e-mails as spam or not spam using the word and character frequencies and the uninterrupted capital lettering data found in the file spambaseshort.csv. To this end we choose to train a simple perceptron model using 70% of the data available. The model works like this:

$$f = \sigma(w_{0j} + w_i^T X)$$
 ,  $j = 1....K$  (1)

$$sign(C) = \begin{cases} -1 & \text{if } C < 0\\ 0 & \text{if } C = 0\\ 1 & \text{if } C > 0 \end{cases}$$
 (2)

$$w_j = w_j + \lambda (y_i - \hat{y}_i) x_{ij} \tag{3}$$

We have the that the predicted output can be computed as (1) where K is the amount of iterations needed, the combination function is given by  $C = w_j^T X$ ,  $\sigma$  is the activation function which is sign (2) in our case and  $w_j$  are the weights. The simple perceptron learning algorithm computes the weights as (3) where  $y_i - \hat{y}_i$  is the difference between predicted and true output,  $\lambda$  is the learning rate and we compute new weights until the misclassification rate has stopped decreasing. The implemented function can be seen in the appendix. The settings to be used for the model are exactly as described in the lab instructions. We train two models, one with set.seed(7235) and one with set.seed(846) and find the misclassification rate of the test data in each case.

```
## output
## truespam -1 1
## -1 77 4
## 1 7 50

## [1] "Misclassification rate for test data: 0.0797"

## output
## truespam -1 1
## -1 77 4
## 1 10 47
```

## [1] "Misclassification rate for test data: 0.101"

We see that the simple perceptron model works well for this data set, with not very bad misclassification rates for the two seeds. Let us now compare the test misclassification rates with those produced by classification performed by a logistic regression model classifier.

```
## testresult
## testspam -1 1
## -1 71 10
## 1 7 50
```

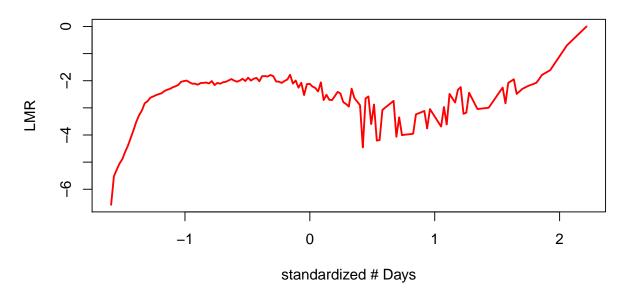

#### ## [1] "Logistic regression misclassification rate: 0.123"

From my vantagepoint, it looks as if the simple perceptron model performs slightly better than the logistic regression model in terms of misclassification rate.

### Assignment 2

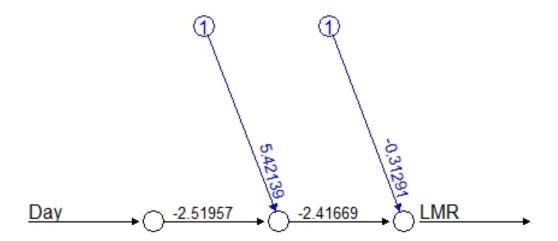

We wish to perform nonlinear MLP neural network regression of Log mortality rate of fruitflies upon standardized day variable in the dataset mortality.csv using the package neuralnet. The line plot of the data looks like this:

# Log mortality rate of fruit flies vs standardized # days

A first impression suggests that the regression fit indeed will not be linear, but rather non-linear.

We now fit neural networks with one, two, four and five hidden nodes, all using set.seed(7235), and investigate their fits, relative SSE and steps taken.

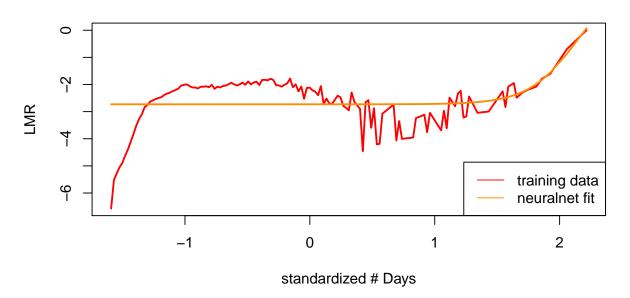

Error: 49.703647 Steps: 607

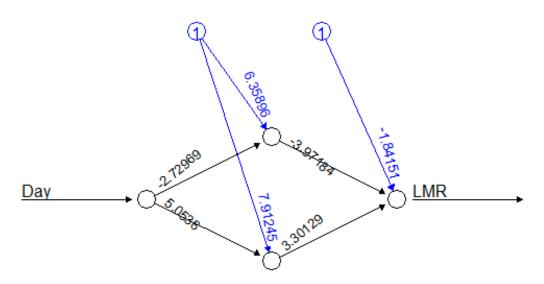

The resulting equations of the neural network with one hidden node are, with linear output:

$$Z = \sigma(5.4214 - 2.5196X)$$

$$y = -0.3129 - 2.4167Z$$

### One hidden node neuralnet fit

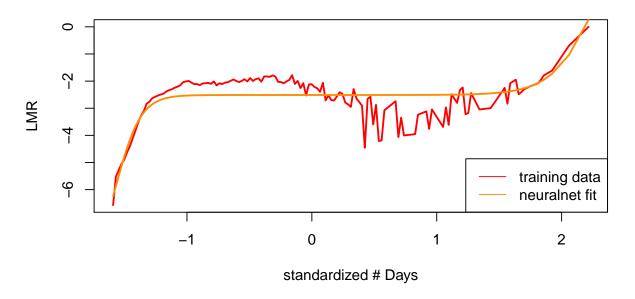

Error: 23.251744 Steps: 1859

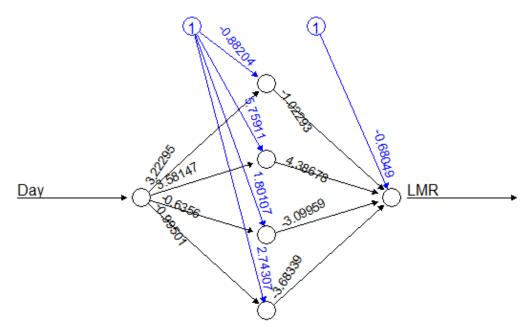

The resulting equations of the neural network with two hidden nodes are, with linear output:

$$Z = \sigma \left( \begin{pmatrix} -2.7297 \\ 5.0538 \end{pmatrix} + \begin{pmatrix} 6.3590 \\ 7.9125 \end{pmatrix} X \right)$$

$$y = -1.8415 - 3.9718Z_1 + 3.3013Z_2$$

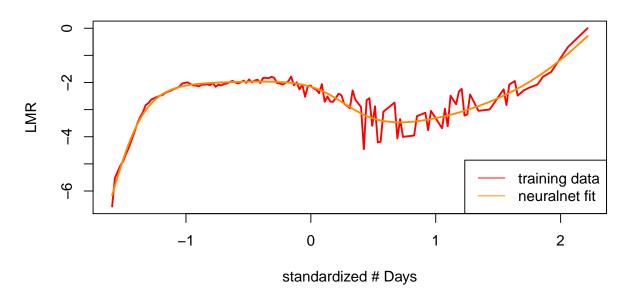

# Two hidden nodes neuralnet fit

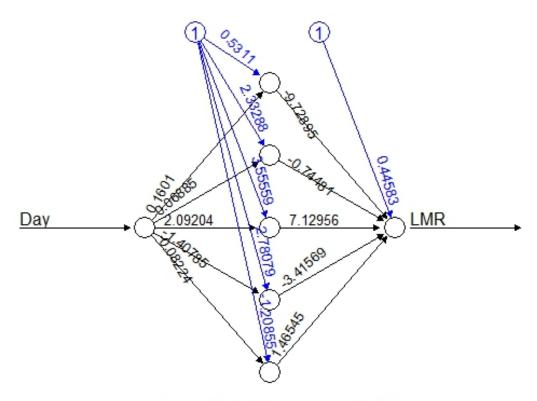

Error: 6.212279 Steps: 2355

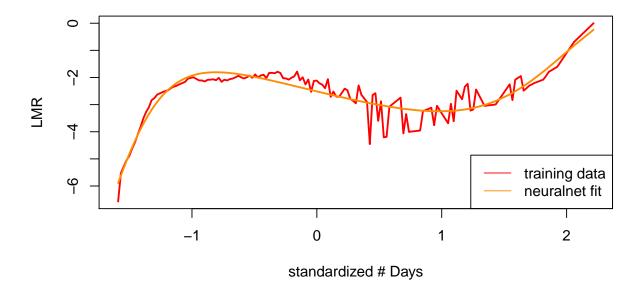

# Four hidden nodes neuralnet fit

Error: 9.289007 Steps: 8201

#### Five hidden nodes neuralnet fit

We clearly see that the more nodes, the smaller the SSE becomes up to four hidden nodes. The neural network fit becomes overfitted with more hidden nodes than four. We also see that the number of steps taken increase with number of hidden nodes. It appears as if the first two models do not produce good fits, while the last two models do produce good fits. To me, the fit using four nodes looks like the best fit (it also has the best SSE). I'd venture to say that more hidden nodes lead to better ability to fit non-linearities in the fitted curve.

#### Contributions

All group members contributed to the report, which is based on Thomas lab raport. Martina donated the latex equations and helped with interpreting the output and Maxime provided helpful plotting suggestions.

#### Appendix - R-Code
